

Donuts Name Collision Comment

Donuts appreciates the opportunity to respond to comments submitted on the name collision issues.

Executive Summary

So-called “name collision” has been presented to the community as a last-gasp argument for delay in the eight-year new gTLD process. This is regrettable, as name collision is not a threat to the Internet’s infrastructure in the way it has been negatively portrayed.

This comment will demonstrate the opposite—that:

- “name collision” is an existing issue in .COM, without damage to the domain name system (DNS);
- the data shows that collision isn’t the danger it may have been portrayed to be, and the Interisle report is deficient in its findings;
- “collision” existed prior to the introduction of other new gTLDs, again without damage to the security and stability of the DNS or the Internet;;
- mitigation (if needed) can be successfully handled on a case-by-case basis;
- there is no need to delay the program further or measure the root system more than is already planned; and
- the key to understanding name collision is to examine second-level domains, which the Interisle study did not do.

The Scope of Any Perceived Problem

Interisle—by its own admission—was not granted sufficient time to completely study the root system data available to it for name collision. Had the study been more thorough, it would have responsively demonstrated that the magnitude of collision in .COM is far higher than the rate of collision in every new round applied-for gTLD.

In order to make a fair comparison of the relative risk regarding collision, it’s critical to point out that Verisign, as manager of the .COM registry, experiences collision at a rate of at least 2,000 names per day for the studied period in 2013, and at least 16,000 names per day for the study period in 2012 (see below for additional data).

Opponents of the new gTLD program, or those who have commercial interest in opposing namespace expansion, apparently express that collision and non-existing domain (NXD) traffic is acceptable in the current root—especially .COM—but, cynically, that such traffic in other gTLDs (such as .CORP and .HOME) actually threatens lives.¹ Such statements are not only needlessly alarmist, they attempt to create fear and uncertainty where none is warranted.

Notification of Applicants

Prior to the opening of the application window, the Security and Stability Advisory Committee (SSAC) issued SSAC 045² and recommended the applicant would be alerted “during the string evaluation process about the pre-existence of invalid TLD queries to the applicant’s string.” SSAC also recommended “ICANN should coordinate with the community to identify a threshold of traffic observed at the root as the basis for such notification.”

ICANN has set the bar and notified the applicants as SSAC recommended, even if after the conclusion of Initial Evaluation. The SSAC has not recommended that the applied-for TLDs over the bar be delayed or restricted from root entry. Accordingly, advice was followed, and the SSAC has not advised delay.

History of Collision

As DNS creator Paul Mockapetris cites³, the central issue is there are DNS facilities, and simultaneously there are programs that use the DNS. Some software or networks don’t reliably collaborate with the DNS—and has been stated often, such is a business risk assumed by those producers. The DNS is not responsible for reverse-engineering to fit broken software. Any collision problem doesn’t reliably lay with the existence of a new gTLD.

In fact, Mockapetris, in his authoritative experience, shares the fact that 200-some ccTLDs were added to the root without issue. The same position was reliably put forth by the New TLD Applicant Group (NTAG) in its 5 August 2013 comment on name collision, stating:

“A Verisign analysis using data from January 2006, prior to the launch of several active TLDs, found that .xxx received more queries before delegation than any other new TLD. Despite having more queries than all of the TLDs currently under consideration in the ‘Uncategorized Risk’ category, .xxx was delegated in 2011. This TLD launched without incident, and no public complaints or technical issues have been identified since.

In addition, most of the other TLDs listed in Table 1 of the Verisign report, including .asia, .kp, .ax, .um and .cw, also demonstrated much higher numbers of NXDOMAIN responses than all 279 of the ‘uncategorized’ strings, and again all were delegated with no noticeable impact. In fact, the least ‘dangerous’ current gTLD on the chart, .sx, had 331 queries per million in 2006. This is a higher density of NXDOMAIN queries than all but five proposed new TLDs. Again, .sx was launched successfully in 2012 with **none** of the problems predicted by these reports.”

As Mockapetris states, worries about collision have existed since the introduction of the DNS. But, as he further says, and as the Board surely realizes, there is an unprecedented level of caution in the introduction of this round of TLDs compared to previous rounds, or to the introduction of ccTLDs. The introduction of previous TLDs with no impact bears out the fact that this issue is overstated.

Deficiencies in the Interisle Study

This is the chart from the Interisle report that shows the queries to the root (both NXD and non-NXD for the study period (approximately one day) in 2013:

² <http://www.icann.org/en/groups/ssac/documents>

³ <http://www.icann.org/en/news/press/kits/video-mockapetris-15aug13-en.htm>

However, according to our in-depth (with an appropriate amount of time to review the data) study of the same information, we found the following:

Item	Without accounting for TTL	Estimate with accounting for TTL
Existing TLDs	55%	78%
Proposed TLDs	3%	2%
Potential TLDs	19%	10%
Invalid TLDs	23%	12%
	100%	100%

Source: Applicant OARC data study (for 2013)

It appears that Interisle calculated its percentages based on the top 100 TLDs for which the root saw any queries (NXD or Non-NXD). Our study looked at *all* TLDs for which the root saw any queries.

If one accounts for the “time to live” (TTL, or the length of time that an ISP will retain the previous DNS answer), the NXD for applied-for names would be a smaller percent of the overall number of queries than shown in the Interisle report.

The Interisle study did not consider TTL as a factor when calculating ratios for the above pie chart. The TTL for non-existent SLD.TLD names is in fact *half* that for delegated TLDs. Existing TLDs are delegated, and obviously the others aren’t. Because of the half figure for non-delegated TLDs, the system “asks” the root twice as often as the delegated existing TLDs, making an apples-to-apples comparison in a pie chart misleading. The DNS traffic for sparsely queried names at recursive level is nearly directly reflected at the root level. And this is especially true for non-existent TLDs compared to existing TLDs. Comparing those sparsely trafficked names to heavily trafficked names at the recursive level, those heavily trafficked names have much less of their traffic reflected at the root level. These facts not only makes Nx D traffic for non-existent TLDs difficult to compare to traffic at legacy TLDs but also difficult to compare to other non-existent TLDs.

Had we had access to a large sample size of recursive DNS data, we would have been able to get a more accurate approximation, but what we do know is that the NXD traffic to applied-for TLDs is a smaller percent than what is shown in the Interisle report.

Data: Apples to Apples Comparison

It's critical that studies about potential collision focus on metrics that are appropriately comparable.

Measurements in .CORP, .HOME, or other so-called "dangerous" gTLDs can't reliably be measured against existing gTLDs because of a factor that has yet to be mentioned—that in .COM and other incumbent gTLDs, registrations constantly remove some of the NXD traffic. This in fact is a factor that could and should have been examined in the Interisle study.

It is very likely that .COM has NXD traffic at an order of magnitude far higher than .CORP; however, names in .COM are allowed to collide. It's unfortunately difficult to know with certainty, as we did not have reliable access to the .COM nameserver or to a significant sample of recursive data.

Examine the following data regarding existing gTLDs and proposed gTLDs, including the cited .HOME example:

	Percent	Total For category
Existing TLDs (not incl .com)	37.1%	55.0%
.com non-NxD	17.7%	
.com NxD	0.2%	
Proposed TLDs (not incl .home)	0.8%	3.0%
Largest proposed TLDs (.home)	2.2%	
Potential TLDs	19.0%	
Invalid TLDs	23.0%	
	100.0%	

Source: Applicant OARC data study (for 2013)

Donuts calculated .COM NXD traffic by examining each .COM SLD name that received traffic at the root (this is a significant number of SLD .COM names—more than 200 million unique .COM SLDs were tracked) for the period in question (we used the same period and the same OARC data as did the Interisle study) and noted whether or not that SLD.COM was in the .COM zone at the time. For any that were not, the .COM name servers would reply with NXD—we therefore totaled such queries and assigned them as NXD, since we do not have access to the .COM name-server logs. We are assured of the accuracy of this data.

None of the root-level NXD traffic attributed to .COM is for registered names, such as high-traffic sites Yahoo.COM, MSN.COM or Google.COM, as may be seen at the recursive level. **All** NXD traffic that we attributed to .COM comes from unregistered names.

As a delegated TLD, .COM has a TTL twice as long. Therefore for that entire TTL period, any NXD query from a recursive resolver (not the SLD.COM name, but .COM itself) would be cached; therefore the root would not see subsequent NXD queries during the cache period. Due to this, we estimate that the actual NXD queries that .COM is seeing is approximately 10x the level indicated above.

In 2013, .HOME queries accounted for nearly 75% of the total queries for all proposed TLDs. Our preliminary analysis shows that 92% of these queries (92% of the 75%) appear to be from Google's

Chrome browser querying for a random sequence of 10-character SLDs. These strings are random and Google Chrome is relying on the fact that it should return an NXD DNS response. To ensure at least one NXD response, Google Chrome will submit three of these random strings at a time, which significantly increases the query count. Many routers have “.HOME” as a search suffix, so a significant majority of these random 10-character string DNS queries end up at the root under the .HOME TLD. Since these strings are designed to not only be random but also not collide with existing registrations, the likelihood of collision and subsequent risk is low to none.

NXD traffic in 2013 is higher than in 2012 for applied-for TLDs. However, there is *less total traffic* in 2013 compared to 2012. Since the data above is from 2013, and this was after the TLD application window closed and the applied-for TLDs were revealed, its possible some of this additional NXD traffic is due to competitive gaming of the NXD traffic. It may be possible to measure this in the historical data if given enough time (by for example, examining source IP and other patterns in the query data). There are many NXD queries (1.7 million) for SLDs that appear to be random computer-generated SLDs (not including the random Chrome browser 10-letter anomaly, which is much larger) in the 2013 data compared to the 2012 data.

Size of the Existing “Problem”

	During the one day study (approx.) period in 2012	During the one day study (approx.) period in 2013
Number of .COM queries that came to the root for names that are not in the com zone (this is the number of NXD queries for .com coming to the root)	888,569,816	83,565,199
Number of unregistered SLD names that generated the queries above	136,905,037	6,296,463
Number of those names above that produced the NXD queries that were registered within the next month	548,188	58,755
Number of NXD queries those subsequent registered names above represent	28,671,101	1,629,429
Percent of the NXD that was subsequently registered (AND THEREFORE COLLIDED)	21%	26%

Source: Applicant OARC data study (for 2013)

The most significant statistic in the above table is that to reach the “danger” threshold outlined by Interisle, a proposed TLD needs to have received 50,000 queries during the study period. **.COM received more than 80 million.**

A significant number of domain names in .COM are registered each month that have NXD traffic. In fact, 548,000 names in a month (on average, about 16,000 name collisions per day) is more names than most registrars have under management after 10 years of operation. These names are not being

“tasted,” since that was banned before 2012. Its very likely that some registrants are specifically targeting .COM names that have NXD traffic, and Verisign is allowing these name to be registered and therefore colliding with “pre-registered users” of these .COM names (those Internet users who use the name and cause the NXD traffic). These NXD names therefore are being specifically targeted for registration. We note that Verisign sells .COM NXD data for this targeting registration purpose.

If these second-level names were to be disallowed, as they were in the proposed TLDs (TLDs were not in the root during the study period), then .COM NXD traffic would *grow* at approximately 1.6 million queries per month (in 2013). Therefore, the NxN query traffic for .COM appears to be low not only due to the TTL, but also due to the fact that these SLDs names are being registered, reducing the NXD load in subsequent months. In other words, the NXD for .COM for the study period would have been even higher if during the previous months Verisign had not allowed NXD .com names to already collide.

.COM queries

Further to the point above, according to the following table, the number of total queries for NXDs decreased between 2012 and 2013, though .COM queries decreased at a faster rate.

	2012	2013	
Total queries	44.8	37.9	billion
.com queries	16.0	7.9	billion
.com as a percent of the total	36%	20.8%	

Source: Applicant OARC data study (for 2013)

By allowing these so-called collisions, Verisign collected \$4 million in registration fees over the month following the single-day study period, which in fact reduced further collision.

It appears further that during the study period in 2012 that .COM name servers were unusually loaded, as compared to the much lower load seen in 2013. In 2012 .COM had 16 billion queries during the study period, compared to 8 billion (half as much) in 2013.

It is also observed that in 2013, during the study period, the J root received 7% percent of the traffic, but in 2012 the J root had 53%.

Distribution of NXD Traffic for Top-Queried SLDs

There’s a smarter way to examine SLD NXD traffic across TLDs. The following table shows each heavily trafficked SLD in order, and the NXD counts for each across ALL applied for TLDs for the approximately one-day period in 2013 using the OARC data. It also shows the TLDs with the highest subdomain traffic.

For example, 99.98% of all NXD traffic that the “Den” SLD produces goes to “Den.ICE”. If the .ICE registry blocks “Den” (or otherwise mitigates it) then any harm that “Den” SLD traffic *may* create is mitigated. As another example, the “google-10-characters” (as if they were one single SLD) saw the most NXD traffic compared to all other SLDs, and 97% of that traffic goes to .HOME, and 0.7% goes to .CORP. If those processes are blocked in just those two proposed TLDs (or otherwise mitigated, by Google for instance) then that similarly goes away. Further, 99.9% of the second-level name “sap” NXD traffic goes to “.CORP”, while 92% of the SLD “org” traffic (a total of 13.2 million NXD hits) goes to .HOME. Therefore, based on 2013 data alone, blocking those second-level names in these two TLDs will very nearly eliminate 46% of all NXD traffic to **all** applied-for TLDs.

NxD Count for the SLD across ALL applied-for TLDs in the 2013 study period (approx 1 day)	SLD	The TLD where this SLD has the largest NxD traffic	The 2nd largest TLD for this SLD...	3rd TLD...	4th...	5th	6th	7th	8th	9th	10th	11th	12th	13th	14th	15th

NXD Queries By TLD and SLD Before Mitigation

The following graph shows a selection of 11 TLDs for which Donuts has applied. The TLDs represent the top eight—by rank of NXD queries in 2013—and the bottom three (but still in the Interisle “20%”) by the same Interisle ranking.

The NxS for each TLD is plotted in order of highest trafficked to least trafficked SLD, for the top 50 SLDs in each TLD. For example, “sap” is the highest trafficked SLD in the “.CORP” TLD, followed by “Bank.CORP”. We also grouped SLDs, in effect, to comprise one SLD. These grouped SLDs are in all caps below the graph. For example, all two-letter SLDs into “2-CHAR”, and the 10-random-character Google/Chrome SLDs into “GOOGLE-10”. We’ve done so because either the entire group is already blocked from registration, such as 2-CHAR, or easily blocked such as GOOGLE-10. As you can see, the NXD traffic for the top TLDs are heavily weighted toward the very few head SLDs. Blocking these SLDs mitigates any potential issue until other mitigation methodologies are employed (such as source IP mitigation).

We comprised the following groups of blocked SLDs:

- 1) Invalid SLDs, such as TLDs that contain an underscore like “srv”. These are already blocked.
- 2) ASCII Two-character, such as “uk”. These are also already blocked by ICANN regulations.
- 3) All TLDs already reserved or have special rules/control by ICANN, for example, “france”, or “example”
- 4) All SLDs that are prohibited as TLDs, for example “local”, and “arpa”
- 5) All TLDs that are major TLDs, such as “.com” and “.org”
- 6) A list of about 32 SLDs that are technology terms, such as “router”, and “lan”
- 7) A list of major brands that are heavily trafficked across all applied-for TLDs, such as “sap”, “google”, and “msn”
- 8) All SLDs that are a number less than or equal to 255, such as “10”
- 9) A small handful of SLD strings removed on a TLD-by-TLD basis.

TLD	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGLE-10	com	2-CHAR	hitronhub	GOOGL As you can see the NXD traffic would be mitigated if the above nine types of SLDs were blocked across all TLDs. Note that the new “high-count” SLDs are now very esoteric strings with very low NXD traffic.

The .CORP and .HOME Examples

The applied-for .CORP and .HOME gTLDs have been singled out as particularly (potentially) troublesome. Unfortunately, the Interisle report did not examine *second-level names* for either of these gTLDs, which is more likely the source of any issue.

Consider the usage of these names by brand companies. For example, someone searching for Airbus.CORP may have collided already with another TLD, as another TLD could have been in the search suffix list. The existence, therefore, of .CORP *benefits* Airbus by preventing the what may already be leakage of traffic. End-user search via .CORP demonstrates demand for the name’s usage even before its delegation to the root.

New gTLD traffic is similar to NXD traffic in .COM, .UK, and other existing TLDs. In the case of .CORP, some networks append this name in the event of an unsuccessful resolution. For example, if Google.COM weren’t to resolve, even temporarily, a network could try Google.COM.CORP.

However, the reverse is not true. If a user typed in Google.COM, intending to reach Google, the community does not forbid such names from being registered or receiving NXD traffic. If .CORP were in the search suffix list, then Google.COM.CORP must resolve for any harm to occur. Even then, as we said in our prior comment, if the Com.CORP registrant were prohibited from obtaining a certificate, a secure connection to a destination that was unintended would not occur.

In the instance of the term “corp,” the Corp.COM registration exists. As its registrant admits, it generates significant error traffic, likely due to “.com” (or “Corp.COM”) being in the search suffix list for a large number of users. If Corp.COM were to be deleted, Verisign would allow it to be registered again. This significant error traffic (that would otherwise be NXD traffic) to Corp.COM is not causing harm.

Subdomains, Source Traffic, and Brands

Further to the issue of second-level registrations, the careful blocking of but a few are a viable and effective mitigation for potential collision issues.

Blocking certain second-level names is effectively the same as not inserting the “problem” gTLD into the root, as it relates to collision. The registry simply replies to a query with the NXD as it would now.

In the instance of .HOME, setting aside the “Google-10”, many of the second-level names that would cause collision are already disallowed by ICANN, including two-letter names, names with underscores, and certain terms.

Corollary to this point, it’s critical to examine the source of NXD traffic to ensure the collision issue is not inappropriately overstated. For example, as Google itself will document, the Chrome browser defaults to a random 10-letter domain name search in the event of NXD entry—this accounts for over a third of all NXD traffic. If this issue is fixed, a significant percentage of such traffic will cease.

Brands cannot be discounted in this equation. ICANN rules already provide significant difficulty for non-brand holders to secure a branded second-level name that potentially could collide, thanks to the significant trademark abuse mitigation tools in place in new gTLDs that don’t exist in incumbent

gTLDs and ccTLDs. Certainly, it benefits the brand owner to have their names available to them, and to receive the traffic, rather than have them banned from registration in these gTLD outright.

Recommendations

Donuts recommends the following to address name collision:

- On a TLD-by-TLD basis, disallow a small list of second-level names that receive the disproportionately highest share of collision traffic, if not already blocked by ICANN or otherwise mitigated.
- Request that browsers stop generating random lookups (e.g., random 10-letter names).
- On a TLD-by-TLD basis maintain the ban on two-letter names for a period, or until the NxD traffic is mitigated at the second-level for these names
- Maintain the ban on names with underscores and other punctuation.
- Do not attempt to “instrument” the root by delaying new gTLDs to monitor collision—the data on collision clearly is available.
- Collect sources of problem traffic and address the issue directly with ISPs.
- Don’t set up MX records for certain second-level names (e.g., some SLDs in .MAIL) until that is mitigated by other means.
- Disallow a few Internet terms (e.g., POP3, HTTP, etc.) to mitigate such NxD traffic in some TLDs until that NxD is mitigated by other means.
- Disallow existing TLDs as second-level names (e.g., COM, NET, BIZ, INFO) in certain TLDs for a period.
- Name collision mitigation must be addressed directly with applicants and not decided in a vacuum by the Board. Each TLD will have individualized needs for any perceived mitigation.

Conclusion

Our conclusion from the data is that no applied-for TLDs need mitigation, with the possible exception of a very few.

Had Interisle enjoyed the luxury of additional time, its data perhaps would have been more complete and illustrative.

Name collision, however, exists and will continue to exist in legacy TLDs. It does not cause a problem, though the volume is far greater in these existing TLDs than what could be expected in new gTLDs. There is no evidence that points to a need to limit or slow new gTLD development, and this is confirmed by extensive Initial Evaluation activity for security and stability. The Internet can handle the introduction of new TLDs, even TLDs with existing NXD traffic, just as it has done competently in the past.

As Paul Mockapetris stated, technology is not supposed to limit choice. Donuts respectfully requests the Board to honor this tenet of the new gTLD program.
